Rapid Assessment Reference Condition Model

The Rapid Assessment is a component of the LANDFIRE project. Reference condition models for the Rapid Assessment were created through a series of expert workshops and a peer-review process in 2004-2005. For more information, please visit www.landfire.gov. Please direct questions to helpdesk@landfire.gov.

Potential Natural Vegetation Group (PNVG):

Geographic Range

This PNVG is located in East Texas, adjacent to and surrounding Blackland prairie from near the coast extending north to the southern extent of the Cross timbers as described by Dyksterhuis.

Biophysical Site Description

This PNVG occurs on irregular plains of sand to sandy loam Ustalf soils. Soils are shallow to moderately deep.

Vegetation Description

The vegetation is dominated by Post oak (Quercus stellata) and to a lesser extent blackjack oak (Q. marilandica), a minor compontnt of hickory (Carya spp.) also is a constituent. In open conditions the understory and canopy openings are dominated by little bluestem (Schizachyrium scoparium) and various annual and perennial forbs with prevalence dictated by stand density and overstory canopy cover. In closed canopy conditions, groundcover has little to no herbaceous cover and is dominated by oak leaf litter. Other important woody plants include greenbriar (Smilax spp.), sumac (Rhus spp.) and poison ivy (Toxicodendron radicans). Species that may invade include Prosopis glandulosa to the south and Juniperus virginiana and Juniperus ashei.

Disturbance Description

This PNVG is in fire regime group I, with frequent surface fires, both lightning and anthropogenic in origin (Stewart 1951, 2002; Jurney et al. 2004). Frequent anthropogenic fire was important for perpetuation of this type (Stewart 1951, 2002). Further, frequency approaching annual burning is cited in numerous historical references (Denevan 1992; Stewart 1963, 2002). Historic fires have been documented during all seasons (Stewart 2002, Jurney et al. 2004) dependant on the availability of dry fine fuels sufficient to carry a fire and likely edaphic and microsite constraints. Bison grazing likely influenced fire patterns and thus the

landscape patterns. Bison and other grazing/browsing wildlife species preferentially seek out the new growth of recently burned areas affecting patch composition (Fuhlendorf and Engle 2004). Using the fire/bison interaction model first proposed by Steuter (1986) recent modifications propose that anywhere from 1/6 to 1/3 of a 20,000 acre (8,094 hectares) landscape likely burned (Fuhlendorf and Engle 2004). Likely this was less in oak savanna. This caused earlier green-up and increased nutrient content of native grasses.

Adjacency or Identification Concerns

This PNVG is distinct from adjacent blackland prairie that may be either to the west or east or in the adjacent eastern north to south bands bordering oak-hickory-pine.

Scale Description

Sources of Scale Data 🖌 Literature 🗌 Local Data 🖌 Expert Estimate

The landscape was a matrix of woodland and blackland prairie, with some dissection of this type by small rivers and streams. The landscape for this type is 6-8 million acres.

Issues/Problems

Model Evolution and Comments
